Release Overview

Salesforce Contracts has enhanced its contract management with new features for improved efficiency and accuracy. The internal review workflow is optimized for contract authors. By using the document comparison feature, authors can identify differences between two versions of a contract. Both contract authors and template designers can lock sections within documents to prevent unauthorized edits. Template designers now benefit from real-time document generation by using Single Point Requests (SPR). Additionally, the new file-based prompt APIs help contract admins minimize failures during the extraction of contract details from PDFs. They can refine instructions for both predefined and user-defined fields and test the extraction results before creating a contract record.

- [Enhance Document Generation with Single Point Requests \(SPR\) and Omniscrypt](#)
Generating documents in real time often has limits on file sizes and can cause delays and problems because of large volumes of data on client-side processes. The new `docGenerationSample/CoreSingleDocxLWC` Omniscrypt addresses these challenges by using Single Point Requests (SPR) functionality. With the Omniscrypt, you can create documents from Microsoft Word (DOCX) or PowerPoint (PPTX) templates.
- [Control Edit Access to Protect Essential Contract Sections](#)
Template designers and contract authors can lock sections when they're designing the template or authoring the contract. With the section lock feature, you can prevent unintended users from editing and deleting sections and their associated content. For example, in a product sales contract, you can lock the warranty section to ensure that the terms and conditions of the warranty remain unchanged. Locking makes sure that specific sections of your contract remain unchanged, even when multiple parties are involved in the drafting and redlining of the contract. The document generated from a template that has locked sections automatically inherits the lock at the document level.
- [Define and Test Instructions for Better Extraction Results](#)
With the integration of file-based prompt and prompt runtime APIs into Salesforce Contracts, you can define, test, and refine instructions for standard and custom entities. Add detailed descriptions and verify them during the design phase by using the entity extraction mapping framework for better LLM results. Upload PDF files to test extraction asynchronously. In addition, you can change the instructions for each field, test with a small document, and rewrite the instructions as needed without uploading the document again. Then, save results to extraction templates for runtime use. You can

also preview files automatically before runtime to ensure a smoother and more reliable extraction process.

- [Streamline Your Internal Review Processes with Automated Checkout](#)
Refining the checkout process streamlines the internal review workflow by minimizing the steps required for the contract author to kickstart a review. When you initiate an internal review, the active contract document version is automatically checked out, and a new version is created with the status In Review. This new version then opens directly in the Microsoft 365 editor so that you can add reviewers and efficiently manage the review process with your internal team.
- [Identify Differences Between Contract Versions](#)
Contract users can effortlessly compare a contract's current version with any of the previous versions to identify differences introduced during redlining. This feature is available only for DOCX files. The compare feature highlights differences such as content modifications and table edits. After the preview is generated, you can review the differences. For larger documents, the preview generation can take longer, so you can download the comparison document for an offline review.

Single Point Request Document Generation

Business Objective

Customers currently using client-side doc gen need improved scale and performance and the freedom to generate documents without requiring the installation of a managed package.

Use Cases

Traditional client-side based document generation (part of managed package) has limitations in terms of scale and performance. This is resolved by the new Document Generation feature (SPR) that generates DOCX and converts to PDF directly on the *off-core* services. This will help in processing complex documents and higher file sizes. Once the document and PDFs are ready, the files are seamlessly transferred and attached to respective Object entities.

Design Time Configuration

As part of the Winter' 25 Revenue Cloud release, customers will be able to use DocGen and generate documents without requiring use of the Omnistudio managed package. Out of the box, DocGen Omniscript will be available with DocGen license and customers can customize the Omniscript and use it in workflows.

Compare Contract Versions

Business Objective

Customers need to be able to compare redlined versions of a document with any of the previous versions to better understand changes introduced to the document between versions.

Use Cases

The contract documents undergo multiple changes across versions as a part of the redlining process. During these multiple interactions, different document versions might get created. The contract authors need to be able to identify the detailed differences across the versions to verify the contents and accuracy of a final document. When reviewed and approved, the final document can be check-in and sent for customer approvals or signature

Design Time Configuration

Released as part of the Winter' 25 Revenue Cloud solution, customers can now use the document comparison feature to compare a contract's current version with any of the previous versions to identify differences introduced during redlining. This feature is available only for DOCX files. This is included with the base Salesforce contracts licenses and requires no additional licensing

Define & Test Prompt Instructions for Custom Entity Extraction

Business Objective

Customers need to be able to both define the instructions for their prompts and be able to test them with sample documents to review and correct the necessary instructions

Use Cases

With the integration of file-based prompt and prompt runtime APIs, you can define, test, and refine instructions for standard and custom entities. You can add detailed descriptions and verify them during design using the entity extraction mapping framework for better LLM results. You can upload PDF files to test extraction asynchronously.

Design Time Configuration

This feature comes with the pre-existing Contracts AI licenses and doesn't need any additional configuration. As a general flow, the user experience consists of:

1. Uploading PDF files to test extraction asynchronously
2. Change the instructions for each field, test with a small document, and rewrite the instructions as needed without uploading the document again
3. Save the instructions back for using them in entity extractions from contract documents

Configuration and Runtime Video

Lock Contract Sections

Business Objective

Customers need to be able to lock certain sections at the contract level and the template level to prevent any faulty edits during the redlining process. Locking ensures that specific sections of your contract remain unchanged, even when multiple parties are involved in the drafting and redlining of the contract.

Use Cases

Sections and content within these sections can be made non-editable and read-only if the current content needs to be preserved in its original form. For example, in a service contract, the Warranty Section can be locked to ensure that the terms and conditions of the Warranty remain unchanged

Design Time Configuration

The Template Designers and the Contract Authors can use the Lock Sections option to prevent edits and modifications on a given section of the document. The sections locked at the template level can only be unlocked by a Template Designer and the authors who locked the content. The document generated from a template that has locked sections automatically inherits the lock at the document level.
